You can verify that the simplified manager is logging as it should as follows:

```
class SyncTestingSpec ...

  ...
  "record the log" in {
      val testKit = BehaviorTestKit(SimplifiedManager())
      testKit.run(SimplifiedManager.Log)
      testKit.logEntries() shouldBe Seq(              ❶
        CapturedLogEvent(Level.INFO, "it's done"))
  }
  ...
}
```

❶ Proves expectations

The log events are of type `CapturedLogEvent` because the `BehaviorTestKit` maps all real log events to this type. Otherwise, you would have to check a specific implementation, depending on your chosen logging.

Although the `BehaviorTestKit` is useful in certain scenarios, it cannot test scheduled messages or multiple actors. And because one actor is not really an actor, as you learned in the previous chapter, you naturally focus on group interactions in asynchronous environments. Let’s look at how you can test in these circumstances.

4.3 Async testing

Asynchronous testing works with a real `ActorSystem` with parallel executions, where you have no guarantee about the order in which messages arrive. This is a black-box testing style.
