need to intercept them. To do so, you use the `LoggingTestKit`. The other difference is that `LoggingTestKit` doesn't wrap the logging events in a `CaptureLogEvent` like `BehaviorTestKit` does.

Logback dependency

`LoggingTestKit` requires logback dependency. This means adding the following to your build.sbt file:

```
val LogbackVersion = "1.2.3"
libraryDependencies += "ch.qos.logback" % "logback-classic" %
➥LogbackVersion
```

Let's test the same logging feature of the simplified manager that was tested in the synchronous version:

```
object SimplifiedManager {

    sealed trait Command                          ❶
    case object Log extends Command               ❶

    def apply(): Behaviors.Receive[Command] =
      Behaviors.receive { (context, message) =>
        message match {
              ...
          case Log =>
            context.log.info(s"it's done")        ❷
            Behaviors.same
        }
      }
}
```

❶ Protocol

❷ Logging

To use the `LoggingTestKit`, you need to set two things:
