- *Restart*—The actor must be re-created. After the restart (or reboot, if you will), the actor continues to process messages. The rest of the application uses an `ActorRef[T]` to communicate with the actor and continues to use the same reference and, with it, the same mailbox from which the new actor instance will automatically read new messages.
- *Resume*—The same actor instance should continue to process messages. The exception that would cause the actor to crash is logged only by the supervisor.
- *Stop*—The actor must be terminated. It no longer participates in the processing of messages.

You need to take some special steps to recover the failed message, as you learn later when we look at implementing a restart. Suffice it to say that in most cases, you shouldn't reprocess a message because it probably caused the error in the first place.

An example is the case where the `LogProcessor` encounters a corrupted file or an unparseable line. Reprocessing corrupted files can end up in a so-called *poisoned mailbox*—no other message is ever processed because the corrupted message keeps failing. For this reason, Akka chooses not to leave the failed message in the mailbox after throwing an exception; you can do this yourself if you are absolutely sure the message did not cause the error, as you learn later.

Let's recap the benefits of the let-it-crash approach:

- *Fault isolation*—A supervisor can decide to terminate an actor. The actor is removed from the `ActorSystem`.
