An actor affects its children when it is stopped or restarted. Its children are forced to stop in both cases because by default, the actor's supervision is set to stop. This behavior can be changed through configuration. Examples can be found at the end of the section.

Also be aware that it is not only the parents that influence their children or the supervisor that decides the next behavior of its inner actor. It is also possible for each actor to establish a relationship with another actor by observing when that actor is terminated or fails. This is called *watching*.

Let's go through how supervision deals with the actor's lifecycle and its signals under different strategies.

5.3 Supervision strategies and signals

Certain signals are subproducts of a supervision strategy. `SupervisionStrategy.stop` and `.restart` are intertwined with the signals `PostStop` and `PreRestart`.

5.3.1 Uneventful resuming

When a message is processed and throws an exception, the simplest way to deal with it is to resume. With this strategy, the exception is logged, and the message from the mailbox is lost forever.

NOTE It is possible to keep this message, but then you must fix the error by catching both the exception and the message. With this
