```
val behavior: Behavior[Command] = ...

Behaviors.supervise(behavior).onFailure(SupervisorStrategy.stop)
```

5.3.3 Restart and the PreRestart signal

This strategy creates a new incarnation of the same actor definition after a failed message. The process is transparent to the entire system, as the `ActorRef[T]` used as a facade to communicate with the actor is still valid. Any message sent to this actor is stashed and eventually processed by the new instance of an equivalently functioning actor.

Before it is removed, the supervisor sets the actor's next behavior to `Behavior. failed`, which prevents further messages from being processed. The system notifies the actor with a `PreRestart` signal.

Figure 5.9 shows the process from the receipt of the message that raises the exception to the reincarnation of the actor. Here, actor A receives message X and raises an exception X that the supervisor catches. The restart strategy decides on `Behavior .failed` as the next behavior for the actor, and the system sends `PreRestart` before removing the actor. This signal is similar to the `PostStop` signal, giving you some leeway before the stop. Once this signal is processed, the actor is stopped while its mailbox continues to operate as usual, at least as far as receiving messages is concerned. Immediately after the actor is spawned, if it has a `Behavior.setup`, the code in this method is executed before a new message is processed.
