backoff strategy waits a bit longer at each restart until the maximum waiting time is reached. There is also some randomness to prevent all database writers from performing a backoff at the same time. If no backoff has occurred after 15 seconds, the next backoff returns to the minimum.

The processed `Line` may throw an `UnexpectedColumnsException`, but this failure is related to the data, not the actor's state or context. The actor ignores this failure and logs some information about it, while the behavior remains the same. In short, the database writer logs and resumes.

Summary

- Fault tolerance is one of the most exciting aspects of Akka, and it's a critical component in the toolkit's approach to concurrency.
- The philosophy of "let it crash" is not a doctrine of ignoring the possible malfunctions that may occur or the toolkit swooping in and healing any faults.
- You need to anticipate recovery requirements, but the tools to deliver them without meeting a catastrophic end (or having to write a ton of code) are unparalleled.
- Because the actor model is built on messages, even when an actor goes away, the rest can continue to function.
- Supervisor strategies can resume, stop, or restart; the choice is yours, given the requirements in each case. The default is the stop strategy.
