another application, a problem arises. The start of the path is `MyAppl`, but the other application probably has a different configuration root. So, the path to the property has changed. This can be solved by getting a subtree for your new configuration:

```
import com.typesafe.config.Config

val databaseCfg: Config = configuration.getConfig("MyAppl.database")    ❶

val databaseConnectURL: String = databaseCfg.getString("connect")       ❷
```

❶ Gets the subtree by name (used in application-specific code)

❷ References the property relative to the subtree root (used in DBaseConnection)

Using this approach, instead of configuration, you give the `databaseCfg` to `DBaseConnection`. Now `DBaseConnection` doesn't need the full path of the property; it only needs the last part: the property's name. This means `DBaseConnection` can be reused without introducing path problems.

7.1.3 Substitutions

You can also perform substitutions when a property is used multiple times in your configuration, such as the hostname of the database `connect` string:

```
hostname="localhost"                                    ❶
MyAppl {
    version = 10
    description = "My application"
    database {
        connect="jdbc:mysql://${hostname}/mydata"       ❷
        user="me"
```
