❶ Once the ActorSystem is constructed, you can get the config by referencing it using this path.

❷ Gets a property as usual

You've seen how you can use the configuration system for your properties and use the same system to configure the `ActorSystem` that's the backbone of Akka. The presumption in these sections has been that you have only one Akka app on a given system. The next section covers configuring multiple systems that share a single instance.

7.3 Multiple systems

Depending on your requirements, you may need different configurations—say, for multiple subsystems—on a single instance (or machine). Akka supports this in several ways. Let's start by looking at cases where you're using several JVMs, but they run in the same environment using the same files.

You already know the first option: use system properties. When a new process is started, a different configuration file is used. But usually, a lot of the configuration is the same for all the subsystems, and only a small part differs. This problem can be solved by using the `include` option.

Let's look at an example. Let's say you have this baseConfig.conf file:

```
MyAppl {
  version = 10
  description = "My application"
}
```
