In this example, you start with this simple configuration root, which would most likely have one shared and one differing property; the version number is probably the same across subsystems, but you typically want different names and descriptions for each subsystem. For this, you can have another file named, for example, subAppl.conf:

```
include "baseConfig"                    ❶
MyAppl {
  description = "Sub Application"       ❷
}
```

❶ Name of the config file you want to include (no extension)

❷ Provide a new description.

Because the `include` is before the rest of the configuration, the value of `description` in the configuration is overridden just as it was in a single file. This way, you can have one basic configuration and put only the differences in the specific configuration files for each subsystem.

7.3.1 Lifting with Fallback

You can combine configurations that have some paths in common. Prioritize one of them—also called *lifting*—so it is selected over the fallback configuration.

This technique is often used in testing when you only need to override a few properties of the main configuration. For example, you can set `akka.loglevel` to `debug` instead of `info`.

Let’s start with common paths in one file called combined.conf:
