The next section shows how this can be used in the `ScalaTestWithActorTestKit`.

7.4.1 Lifting in tests

You can add a configuration to a test via the `ScalaTestWithActorTestKit` using the test-kit constructor that accepts a `Config`. Here you can use all the options seen so far, with the `ConfigFactory.parseString` alone or any lifting.

For example, a specific configuration can connect to a local database to run tests. But you may want to modify some values for a specific test suite. Let's say you have the following in-memory.conf file:

```
akka.eventsourced-entity {
    journal-enabled = true
    read-journal = inmem-read-journal
}
...
```

You want to set `journal-enabled` to `false` in a specific test suite.

Let's create a test to see this in action. A property is defined with a string in the test itself that overrides a value from the configuration that came from a .conf file.

Listing 7.1 Using a value from the direct configuration

```
class AsyncLogConfigSpec
    extends ScalaTestWithActorTestKit(
      ConfigFactory
        .parseString("""akka.eventsourced-entity = false""")          ❶
        .withFallback(ConfigFactory.load("in-memory")))               ❷
    with AnyWordSpecLike
```
