- `aeron-udp`–Based on Aeron (UDP). Offers better performance than `tcp` in terms of throughput and latency but at the cost of CPU consumption—even if the application does not use the available message rates.

`artery.canonical.hostname` is a unique location defined by an address and a port. If multiple names refer to the same IP address, only one can be used. Consequently, 127.0.0.1:port can be used on local development but not across the network, because it is not unique.

`artery.canonical.port` is the port on which the `ActorSystem` should listen. It is selected automatically—and the value is chosen randomly between certain limits if it is set to 0.

To use this configuration, the project must include the following dependency in its build.sbt file:

```
val AkkaVersion = "2.6.20"
"com.typesafe.akka" %% "akka-cluster-typed" % AkkaVersion
```

With this configuration, you have everything you need to create a cluster.

8.2.3 Starting the cluster

Let’s start the first node by accessing the sbt console and writing down the `ActorSystem`. This is an alternative to writing a file with an `App` and an `ActorSystem` as you have done so far.
