Now you need to start the Akka Management server in each node:

```
import akka.management.scaladsl.AkkaManagement

AkkaManagement(system).start()
```

Adding this code to the `Main` in chapter08a starts the Akka Management server in each node when you run it. Such a `Main` looks like this:

```
import akka.actor.typed.ActorSystem
import akka.actor.typed.scaladsl.Behaviors
import akka.management.scaladsl.AkkaManagement

object Main extends App {

  ActorSystem(Behaviors.empty, "words")     ❶
  AkkaManagement(system).start()            ❷

}
```

❶ Starts the ActorSystem in cluster mode as per the configuration

❷ Starts the Akka Management server

Remember, since this example is running on the same machine, you need to pay attention to the ports: not only `remote.canonical.port`, as before, but also `akka.management.http.port`, which must also be different from the default for all nodes except the first one that is running. Otherwise, you get

```
java.net.BindException: [xyz-address] Address already in use.
```

Do the following to start the first node:

```
$ sbt -DPORT=2551 \
-Dakka.management.http.port=8558 \
```
