```
serialization-bindings {
      "example.countwords.CborSerializable" = jackson-cbor      ❶
}
```

❶ Binds the trait example.countwords.CborSerializable to the jackson-cbor serializer

With this configuration, you must ensure that you have such a trait in your application and mix it with the messages you need to serialize. In this chapter's example, that means all messages going from the master to workers or vice versa. The `example.countwords.CborSerializable` trait is nothing more than a placeholder that points to the serialization of your choice. Here is the implementation:

```
package example.countwords

trait CborSerializable
```

For example, as you saw in the master, you need to use the trait with the message that requires serialization:

```
object Master {
  ...
  final case class CountedWords(aggregation: Map[String, Int])
      extends Event
      with CborSerializable
  ...
}
```

Another serialization library is Google Protocol Buffers. This option has better throughput than Jackson and very flexible schema development. The downside is that it requires more work to set up and maintain. Whichever serialization you choose, it's important to consider schema evolution (but that's a topic in itself and not specific to Akka, as you may know). In most cases, the serialization chosen in this example is sufficient to use in production.
