- Akka Projections are Akka Streams that can consume from Kafka or a database transformed and written to Kafka, a database, or a gRPC service.
- With an Akka Projection, you can read the journal and create a view from it. This way, you can group the events of the journal in a view optimized for consumption and meet different business needs with each view, independent of the writing of the journal.
- The main components of a projection from database to database are the `EventSourceProvider` to read the journal and the handler to write the view that implements a `JdbcProjection`.
- The `ShardedDaemonProcess` allows you to distribute behaviors in a cluster, similar to sharding. And it is what you use to scale a projection.
