The server path, the endpoint, is defined by a `Route`. To create it, use `path("ping")` and listen for HTTP `GET` methods to respond —`complete`—with “pong”:

```
import akka.http.scaladsl.server.Route
import akka.http.scaladsl.server.Directives._

object HttpServer {
   ...

     val route: Route =
        path("ping") {          ❶
          get {                 ❷
            complete("pong")    ❸
        }
      }

   ...
}
```

❶ Server route path

❷ HTTP method

❸ Returns a value to the client

`path` is a directive available through `Directives`, as you can see in the imports, but let’s not get into directives yet. If you bind this route to a specific host and port, you have an Akka HTTP server:

```
import akka.http.scaladsl.Http
import akka.http.scaladsl.Http.ServerBinding

object HttpServer {
  ...

     val bindingFuture: Future[ServerBinding] =
        Http().newServerAt("localhost", 8080).bind(route)
  ...
}
```
