- Create the final result using `complete`, or `redirect` a request.

This chapter gives examples of the last three.

11.1.4 Route directives

Routes are like the branches of a tree. You use them to define how each request is processed. Depending on the request, the route traverses one branch or another until the request completes—or fails—and returns a response to the caller.

THE COMPLETE METHOD

The previous example returned “pong” inside an HTTP response with `200 OK`. You don’t have to stick to `200 OK` (that’s the default value); `complete` has many constructors to create the `HttpResponse`. You can use different media types, status codes, and headers to create the `HttpResponse` along with the object you want to send back—the entity (`HttpEntity`):

```
complete(HttpResponse(entity = "pong"))                          ❶

complete(HttpResponse(                                           ❷
          201,
          entity = HttpEntity(ContentTypes.`application/json`, "created"))

complete(StatusCodes.OK,
           headers = List(`Content-Type`(`text/plain(UTF-8)`)),  ❸
           entity =  "pong")
```

❶ Creates an HttpResponse

❷ Specifies a more elaborate entity with HttpEntity
