You will see a tilde in many Akka HTTP applications, but it is not recommended as an operand. You can achieve the same with the operand `concat` and avoid the drawbacks. The problem with a tilde is that there is no compilation guarantee. You can use it, but if you forget to add it, the code will still compile but will interpret only the last `route` statement.

To avoid this pitfall, you can use `concat` with a comma to separate the route directives. If you forget the comma, the compiler will alert you:

```
object HttpServerConcat {
   ...

    val route: Route =
      path("ping") {
        concat(                ❶
          get {
            complete("pong")
          },                   ❷
          post {
            println("fake storing op")
            complete("ping stored")
          })
      }
   ...
}
```

❶ Concatenates the route directives

❷ Route directives separator

`concat` lets you create routes by nesting paths and directives like this:

```
val route =
  path("a") {
    concat(
      path("b") {
        concat(
```
