❷ Business objects of the actor

❸ Protocol of the actor

❹ Initializes the container with an empty list of cargo

❺ Adds cargo

❻ Gets cargos

First, let's look at the expected behavior. The following snippet shows how to send two items of cargo to a container and retrieve their status:

```
$ curl -XPOST "localhost:8080/cargo?entityId=1&kind=sack&size=12"      ❶
Adding Cargo requested

$ curl -XPOST "localhost:8080/cargo?entityId=1&kind=bigbag&size=4"     ❶
Adding Cargo requested

curl localhost:8080/cargo?entityId=1                                   ❷
{"cargos":[{"kind":"bigbag","size":4},{"kind":"sack","size":12}]}
```

❶ Adds cargo to the container

❷ Retrieves cargos from the container

To make the container accessible from outside the `ActorSystem`, you have to create an endpoint by doing two things:

1. Transform the request into a case class using the directive `.parameters`.
2. Transform the response into a JSON format using `akka-http-spray-json`. You do so with marshalling/unmarshalling.

TRANSFORMING THE REQUEST
