project is compiled—for example, with sbt compile—the `AkkaGrpcPlugin` creates all the classes representing these messages and RPC calls.

From each message in the file, the plugin creates the Scala classes `Cargo`, `AddCargo`, and `AddedCargo` using the third-party Scala library `scalapb`, which is included in the `AkkaGrpcPlugin`. The part of the plugin specific to Akka creates a `ContainerClient` and a `ContainerService`. You can find all the created classes in the chapter11b/target/scala-2.13/akka-grpc folder after you compile the code.

In that folder, the `ContainerClient` is a prebuilt client that you can use to call the service programmatically. The `ContainerService` is a prebuilt server that you need to extend to implement your own server that you can later bind like a route in Akka HTTP.

The following listing shows part of the prebuilt implementation of this service. The trait defines the gRPC call `addCargo` from the .proto file, and a descriptor indicates that it is a unary call, a one-to-one request response.

Listing 11.6 gRPC unary definition of the call

```
// Generated by Akka gRPC. DO NOT EDIT.
...

trait ContainerService {

  def addCargo(in: example.container.grpc.Cargo):
     scala.concurrent.Future[example.container.grpc.AddedCargo]
}

object ContainerService extends akka.grpc.ServiceDescription {
```
