You can run this server by executing in the command line at the root of the Git repository: sbt “chapter11b/run”. Then use the command line to send a message as follows:

```
$ grpcurl -plaintext -d '{"kind": "bigbag", "size": 2}' localhost:8080 \
    ContainerService/AddCargo
{
   "ok": true    ❶
}
```

❶ Result

Here, `grpcurl` uses `-plaintext` to signal that it is not using Transport Layer Security (TLS). With `-d`, you can add the input data. Then comes the URL localhost:8080, and finally, the RPC `service` name and `/rpc` name from the .proto file.

## *11.2.6 Akka gRPC with an actor*

Let’s add the container actor to back up the state, just like in the Akka HTTP example. To do this, you need to modify the .proto file accordingly, adding the entity ID when adding the cargo so it can be created and retrieved.

**NOTE** The source code for this example is available at www.manning.com/books/akka-in-action-second-edition or https://github.com/franciscolopezsan cho/akka-topics/tree/main/chapter11c. You can find the contents of any snippet or listing in the .scala file with the same name as the class, object, or trait.

**Listing 11.8 .proto file with a new getter RPC call**
