```
message CargoEntity {                                          ❶
      string entityId = 1;
      string kind = 2;
      int32 size = 3;
}
message AddedCargo {
      bool ok = 1;
}
message EntityId {
      string entityId = 1;
}
message Cargo {                                                ❷
      string kind = 1;
      int32 size = 2;
}
message Cargos {
      repeated Cargo = 1;                                      ❸
}
service ContainerService {
      rpc AddCargo(CargoEntity) returns (AddedCargo) {         ❹

      rpc GetCargos(EntityId) returns (Cargos) {}              ❺
}
```

❶ This is like the previous Cargo, but it has an entityId property.

❷ Now only used as a returning object, not as an input to AddCargo

❸ Cargos have a collection of Cargo. The key “repeated” implements a collection.

❹ Previous RPC call with a new input CargoEntity

❺ New RPC call for getting cargo by entity ID

The previous `Cargo` is now only used by the new RPC call `GetCargos`. In the current .proto file, you could optimize `CargoEntity` and reuse `Cargo` inside it, but that would make it difficult to manipulate on the Scala side. If `CargoEntity` had a `Cargo` type field, you would have to deal with an `Option[Cargo]` when manipulating it. That’s not bad, but for simplicity, let’s leave it out.
