```
      "kind": "bigbag",
      "size": 2
    }
  ]
}
```

❶ Adds one cargo

❷ Adds another cargo

❸ Retrieves the total cargo

You now have a complete picture of how to use Akka gRPC as a port for your `ActorSystem`. This chapter covered how to create servers with Akka so clients can connect through HTTP/1 and with gRPC through HTTP/2. In the next chapter, you put most of what you have learned so far into practice to implement a betting house.

Summary

- Akka HTTP lets you create servers—also called ports in Akka—by defining their paths, the parameters they accept, and other directives to create the routes bound to an Akka HTTP server.
- Akka HTTP provides serialization for the actor's messages via JSON formatters. You can assemble the specific serializer you need—also called a marshaller—from the basic `jsonFormats`.
- With Akka gRPC, you can also create servers, but using protobuf files. When compiling the code, these files automatically generate Scala code that implements the messages and interfaces of the service. The implementation creates the marshallers out of the box.
