RPC calls. Or you can query the status of a market as follows:

```
grpcurl -d '{"marketId": "1243"}' -plaintext localhost:9002 \
 MarketService/GetState
```

With this, you have seen in this chapter how to create the first part of a microservice in Akka, creating entities and their business logic and adding endpoints. Chapter 13 takes an in-depth look at clustering so you can deploy an Akka application in Kubernetes.

Summary

- You create a betting house by implementing the following:
    - The bet, market, and wallet as persistent sharded actors
    - Command handlers and event handlers for each actor, using the behavior primitives to define the business logic as a finite state machine
    - Akka endpoints to allow access to the actors from outside the `ActorSystem`

Creating complex actors often requires writing a set of commands that are only used internally by the actors to meet specific business needs, such as the validation in the bet that `ask`s the market and `tell`s the wallet.
