```
val AkkaVersion = "2.6.20"
val AkkaManagementVersion = "1.1.4"

libraryDependencies ++= Seq(
  "com.lightbend.akka.management" %% "akka-management-cluster-bootstrap" %
[CA]AkkaManagementVersion,
  "com.typesafe.akka" %% "akka-discovery" % AkkaVersion
)
```

`akka-discovery` may not be needed because `akka-management-cluster- bootstrap` transitively depends on and retrieves it along with many other modules like `akka-cluster` and `akka-management`. However, explicitly adding `akka-discovery`—and some of the other modules—is safer because it saves you from having different versions loaded from the various modules that transitively depend on it. If you let each module import its `akka-discovery` version—or any other, for that matter—you may end up with different versions and get a warning or even an exception when loading the classes.

13.1.1 Clustering in local

Now you can set the following to create a local cluster:

- Set `akka.actor.provider` to `cluster`.
- Set the `discovery` method to find the services—the nodes—by specifying the `ActorSystem` name and the IPs and ports of the nodes.
- Set Akka Management to expose the nodes so that the `discovery` method can find them.
