```
dockerExposedPorts := Seq(8558, 2552)                ❸
dockerBaseImage := "adoptopenjdk:11-jre-hotspot"     ❹
```

❶ Version of the app used to tag the container

❷ Packages the app as a Java application on a container

❸ Opens ports to allow node communication

❹ Base Docker image where the app will run

You enable these two plugins:

- `JavaAppPackaging`—An archetype
- `DockerPlugin`—A format plugin in the `sbt-native-packager` sense

The archetype is responsible for what is packaged, the type of content, and its internal structure (hence the name). The format plugin determines how the content is packaged, the form it takes, and its external structure—the image.

`JavaAppPackaging` packages the project into a Java application that places all the JAR dependencies on the classpath. This project must have a class with a `main` executable method to create the entry point. You could use `JavaServerAppPackaging` instead, which provides additional features such as the ability to select the user (called a *daemon*) that runs the application, but we'll keep things as simple as possible here.

Before creating the image, make sure the project contains the necessary configuration:

```
akka.management {
      cluster.bootstrap {
            contact-point-discovery {
              discovery-method = kubernetes-api    ❶
```
