```
            }
      }

      http{
            port = 8558                              ❷
            bind-hostname = "0.0.0.0"                ❸
      }
}
```

❶ Sets the Kubernetes API as the discovery method

❷ Binds to this port

❸ Binds to all IP addresses of this host

With this configuration, you offload node discovery to the Kubernetes API instead of configuring it for fixed IPs. You must also set Akka Management to port 8558 and host 0.0.0.0 to enable the readiness and liveness probe endpoints.

NOTE 0.0.0.0 means the service listens on every available interface. For example, if the host has two IP addresses, 192.168.1.1 and 10.1.2.1, a server running on the host and listening on 0.0.0.0 is reachable on both IPs.

Now you can build the JAR file and put it into a Docker container. To do so, you use the `DockerPlugin`. This format plugin defines the outer structure as a Docker image and lets you set parameters like `dockerExposedPorts` and `dockerBaseImage`. There are quite a few of these parameters, but these two are enough to create the Docker image you need. You can do this from the chapter13b folder of the Git repository: at the command line, enter `sbt docker:publishLocal`. The output of this command displays the name of the build image:

```
[info] Built image chapter13b with tags [0.1.0-SNAPSHOT]
```
