13.2.2 Kubernetes deployment

To create the `Deployment`, you need to do a few things you can break down into parts:

1. Set the Docker image.
2. Set the node discovery.
3. Set the liveness/readiness.

You can set the Docker image, the number of replicas, the name of the deployment, and the policy for pulling images as follows:

```
apiVersion: apps/v1
kind: Deployment
...
spec:
  replicas: 3                                                    ❶
...
  template:
    ...
    spec:
      containers:
      - name: testing-bootstrap13b                               ❷
        image: my-docker-registry/chapter13b:0.1.0-SNAPSHOT      ❸
        imagePullPolicy: IfNotPresent                            ❹
```

❶ Number of pods

❷ Base name of each pod

❸ Route to the image

❹ Pulls the image only if it is not present

This deployment creates three pods, each of which has the setting defined in the `template`. These three pods are named `testing-boostrap21-[deployment-id]-[[0-9a-z]{5}]` and contain the Docker image, which Kubernetes can obtain from Docker Hub if it is not present yet in its local repository.
