With this background, let's go back to Akka discovery, where you have three options. You can add them in Akka Bootstrap's reference.conf file:

```
akka.management {
      cluster.bootstrap {
                contact-point-discovery {

    # Define this name to be looked up in service discovery for
    ➥"neighboring" nodes
    # If undefined the name will be taken from the
    ➥AKKA_CLUSTER_BOOTSTRAP_SERVICE_NAME
    # environment variable or extracted from the ActorSystem name
     service-name = "<service-name>"                                    ❶
     service-name = ${?AKKA_CLUSTER_BOOTSTRAP_SERVICE_NAME}             ❶

      ...
}
```

❶ Order of reading: service-name environment variable, ActorSystem name

In order of precedence, you can specify what the Kubernetes API looks for such that it matches `template.metadata.label` with one of the following:

- *The* `service-name`—That is, `akka.management.cluster.bootstrap.contact-point-discovery.service-name`, which you need to define in your Akka configuration file.
- *The* `AKKA_CLUSTER_BOOTSTRAP_SERVICE_NAME` *environment variable*—You can define this in the Kubernetes deployment.
- *The name of your* `ActorSystem`—You can define this in the source code of your application when creating the guardian.
