Whichever option you choose becomes the value of `%s` in the following Akka Bootstrap default configuration:

```
discovery {
      kubernetes-api {
                pod-label-selector = "app=%s"     ❶
      }
}
```

❶ %s is set based on your choice.

The previously shown deployment file uses the option `AKKA_CLUSTER_BOOTSTRAP _SERVICE_NAME` to avoid being bound to the project source code. You don't have to worry about setting the service name in application.conf or using the `ActorSystem` name. This way, the source code remains independent of the deployment. If you need to change the deployment name in the Kubernetes cluster later, you don't need to rename the `ActorSystem` or change the configuration and then rebuild the image.

NOTE You set `AKKA_CLUSTER_BOOTSTRAP_SERVICE_NAME` by referencing the deployment itself. This variable gets its value from `template.metadata .labels`, which is `testing-bootstrap13babc`.

Finally, readiness and liveness are set via the deployment by specifying the endpoints where Kubernetes checks if the pod is ready and alive. Readiness can be used to check whether the pod is accepting traffic, while liveness checks whether it is responding in a timely manner. Here you use the same endpoint for both checks. (For more information about readiness and liveness, see http://mng.bz/Q81Q.)
