13.2.5 Service account

You can use the default SA to create the `RoleBinding`. However, it is recommended to create a different SA to bind the `Role` and the `Deployment`. To do this, you only need to create the SA by entering its name as follows:

```
kubectl create serviceaccount my-cluster
```

Then add the following reference to the `Deployment`:

```
apiVersion: apps/v1
kind: Deployment
metadata: ...
spec:
  template:
    metadata: ...
    spec:
      serviceAccountName: my-cluster
      containers: ...
```

Finally, you have everything you need to deploy the application to a Kubernetes cluster. You can do this in Minikube, which you installed earlier (see appendix A), by running the following commands from the root of folder chapter13b:

```
$ minikube start
...
Done! kubectl is now configured to use "minikube" cluster and "default"
➥namespace by default

$ kubectl create ns akka-cluster                                    ❶
namespace/akka-cluster created

$ kubectl -n akka-cluster create serviceaccount my-cluster          ❷
serviceaccount/my-cluster created

$ kubectl -n akka-cluster apply -f roles.yml                        ❸
```
