`after=20s`. During this time, at least one group of members must see the same thing before a decision can be made.

The network may be unstable, and perhaps no group can agree on a view of the cluster. When this happens, `akka.cluster.split-brain-resolver.down-all-when-unstable` comes into play. By default, the timeout is 15 seconds. If no decision can be made in `stable-after + down-all-when-unstable`, the network is considered unreliable, and all nodes are shut down.

13.3.2 SBR strategies

The strategies available in SBR are the following:

- `Keep-majority`—The default value. The cluster with the smaller number of nodes `DOWN`s all its nodes and stops:
    - *Recommended for*—Resizing the cluster with minimal operating costs.
    - *Options*—You can filter the number by role.
    - *Corner case*—If each split cluster contains the same number of nodes, all clusters are terminated.
