```
val mySingletonActor = singletonFactory.init(wrappedBehavior)
```

It doesn’t matter how often you run this line of code in your application; there will only ever be one instance available in the cluster. Remember, this actor is not persistent; it loses its state every time it is moved from one node to another. You need to add a persistence mechanism yourself to make its state durable.

Summary

- Akka Cluster Bootstrap allows you to eliminate seed-node configuration and make cluster creation dynamic. You can still use fixed IPs with `.cluster .bootstrap.discovery-method = config`, or you can use dynamic Kubernetes configuration with `.discovery-method = kubernetes-api`.
- Package the application in a Docker image using the plugins `JavaAppPackaging` and `DockerPlugin`.
- Use Akka Kubernetes Deployment to set the `AKKA_CLUSTER_BOOTSTRAP _SERVICE_NAME` environment variable to find the pods belonging to the cluster in combination with `.cluster.bootstrap.contact-point-discovery .service-name`.
- Use Akka Management HTTP endpoints to set the readiness and liveness probes to check if the pods in the deployment are ready to accept traffic and are alive (that is, ready to respond in a timely manner).
