The `config` points to the default Kafka Streams configuration (http://mng.bz/Op5O), and you need the `ActorSystem` to retrieve it:

```
object ConsumerPlainSource {
  ...

  implicit val system = ActorSystem(Behaviors.empty, "consumerOne")     ❶

  val config = system.settings.config.getConfig("akka.kafka.consumer")
  ...
}
```

❶ Implicit system to provide the materializer to the stream

The `ActorSystem` allows you to load the configuration, and making it implicit lets you use it to run the Akka Streams application, as you see at the end of the example. Using the `system` to load the default configuration for the Akka Kafka consumer gives you all the settings, such as `poll-interval`, `commit-timeout`, `enable.auto.commit`, and a few more. The default values are reasonable to start with.

When you set properties in `akka.kafka.ConsumerSettings`, you have access to the underlying Apache Kafka object `org.apache.kafka.clients.consumer.ConsumerConfig`. Therefore, you can configure all the settings of an Apache Kafka consumer.

NOTE For more information, see http://mng.bz/6Djp.

With these settings, you can create a plain Alpakka source and add the topic you want to read from:
