- `maxInterval`—Maximum interval between commits. Default: 10 seconds.
- `maxParallelism`—Parallelism for async committing. Default: 100.

Two things can happen when processing messages: you process more than the maximum batch per max interval, or you don't. For example, by default, if it takes 20 seconds to receive 100 messages, the flow commits after the first 10 seconds. Or if the flow receives 2,000 messages per second, two batches of 1,000 messages per second are committed in parallel.

After the flow, you can use the drain control materialization to drain the stream before shutting it down:

```
object ConsumerCommittableSource {
  ...

  Consumer
   ...
   .toMat(Sink.seq)(DrainingControl.apply)
   ...
}
```

With this feature, you can shut down the stream while waiting for all the messages in flight to be consumed. This way, you avoid reprocessing messages that have already been consumed by the source but not fully processed and committed.

Putting all of the preceding information together, it looks like this:

```
import akka.kafka.scaladsl.Committer
import akka.kafka.scaladsl.Consumer.DrainingControl
import akka.kafka.CommitterSettings
import akka.kafka.ConsumerMessage.CommittableMessage
```
