```
          new StringSerializer(),
          new StringSerializer())
        .withBootstrapServers("127.0.0.1:9092")
```

The remaining producer settings from reference.conf in `akka-stream-kafka` are sufficient for now.

Having a look at the `plainSink`'s signature may be helpful:

```
package akka.kafka.scaladsl

object Consumer {
  ...

  def plainSink[K, V](settings: ProducerSettings[K, V])     ❶
      : Sink[ProducerRecord[K, V], Future[Done]]
  ...
}
```

❶ K and V are the types of Key and Value.

Once you pass in `producerSettings`, the function returns a `Sink` that expects elements of type `ProducerRecord` and returns a `Future` that is `Done` when the stream is finished.

When you wrap the elements in `ProducerRecord`, you can specify the target topic. So, you can specify different topics for different messages if you want to fan them out. For example, elements that pass validation are routed to one topic, while elements that don't are routed to another. Another option is to write each item to more than one topic. You can put all this together in the following test.

Listing 14.2 `plainSink` producing to Kafka from the `KafkaSpec` test
