```
import org.apache.kafka.common.serialization.StringSerializer
import org.apache.kafka.clients.producer.ProducerRecord

class KafkaSpec ... {
  ...

  "a producer" should "write to Kafka" in {

    val config =
      system.settings.config.getConfig("akka.kafka.producer")            ❶

    val topicDest =
      system.settings.config.getString("kafka.test.topic")               ❷

    val producerSettings = ProducerSettings(                             ❸
      config,                                                            ❸
      new StringSerializer(),                                            ❸
      new StringSerializer()).withBootstrapServers("127.0.0.1:9092")     ❸

    val done: Future[Done] = Source(1 to 10)
      .map(_.toString)
      .map(elem => new ProducerRecord[String, String](topicDest, elem))  ❹
      .runWith(Producer.plainSink(producerSettings))                     ❺

    Await.ready(done, 3.second)
  }
  ...
}
```

❶ Loads defaults from reference.conf from Alpakka Kafka

❷ Reads the destination topic from the project's configuration

❸ Sets the connection

❹ Creates a record to push to Kafka

❺ Executes the producer to Kafka

You can see this in action by listening to the `test` topic. Enter the following at the command line:

```
kcat -C -b localhost:9092 -t test
```
