`-C` sets up `kcat` as a consumer. Then you can run `KafkaSpec` to push records to the topic by entering the following in the root of the Git repository:

```
sbt -Dkafka.test.topic="test" "chapter14/testOnly *KafkaSpec"
```

Here's the output:

```
hello     ❶
hi        ❶
1         ❷
2
3
4
5
6
7
8
9
10        ❷
% Reached end of topic test [0] at offset 12
```

❶ Previous message from other runs

❷ Messages from KafkaSpec

Because you're using the same topic as in the consumer example, you also see "hello" and "hi" and possibly more if you've tested further.

14.2.2 At-least-once delivery guarantee

To read from and write to Kafka, you can combine the `CommittableSource` with a `CommittableSink`. Let's look at the latter, together with its `Envelope` and `passThrough`.
