Before reading an actual CSV file, let's begin with a `Source` containing some data and a `Flow` in charge of parsing each line. For a CSV connector—and most other connectors—Alpakka produces a `Source[ByteString]`. A `ByteString` is a binary tree of bytes representing strings. It is immutable, provides more performance than a `String`, and is thread-safe. In the following listing, these bytes are extracted from a single `ByteString` passed as input, which is serialized as UTF-8 by default.

Listing 14.5 Simple source and parsing

```
import akka.stream.alpakka.csv.scaladsl.CsvParsing
import akka.util.ByteString
...                                                                    ❶

class CSVSpec
    extends AnyFlatSpec
    with Matchers {

  implicit val system =
    ActorSystem(Behaviors.empty, "alpakkaExamples")                    ❷

  "A CSV Source" should "be readable" in {

    val result: Future[Seq[List[ByteString]]] =
      Source
        .single(ByteString("Alice,Pleasence,19\nBob,Marley,30\n"))     ❸
        .via(CsvParsing.lineScanner())                                 ❹
        .runWith(Sink.seq)

      ...
  }
}
```

❶ Remaining imports

❷ Required ActorSystem to run the Stream

❸ Source of one ByteString
