- The .proto definition of the service
- An implementation of the service
- An HTTP server to expose the service

With this service, you can send a market ID to get a response with the total for each result. The bet.proto definition is as follows:

```
message MarketIdsBet {
      string marketId = 1;
}
message SumStakes {
      repeated SumStake sumstakes = 1;
}
message SumStake {
      double total = 1;
      int32 result = 2;
}

service BetProjectionService {
      rpc GetBetByMarket(MarketIdsBet) returns (SumStakes) {}     ❶
}
```

❶ Service to retrieve the list of totals per result per market

`SumStakes` can display a table with *n* rows, each one a `SumStake`. For the example, the Liverpool vs. Real Madrid table has three rows.

This .proto file generates the service interface for you, and then you need to implement it. In its implementation, you can use the `ScalaJdbcSession`—added to the scope in `Main`—to access the database and the repository implementation to call the `SELECT` query. This service needs to implement the method `getBetByMarket`:

```
class BetProjectionServiceImpl ... {
  ...
```
