```
        new ByteArraySerializer)

    val sendProducer = SendProducer(producerSettings)(system)
   ...
}
```

❶ These settings read the rest of their properties from akka.kafka.producer in the .conf.

Any property added to `akka.kafka.producer` in the configuration is passed to the producer settings.

15.3 Deployment

Once the code and configuration are ready, you can deploy locally or to Kubernetes. Let's see how.

15.3.1 Running local

To start the Postgres database and Kafka, execute the following at the command line from the betting-house/local-deployment folder:

```
docker compose up
```

Then apply all the SQL files in the betting-house/common-deployment folder: akka-persistence.sql, akka-projection.sql, and bet-projection.sql. When you are asked for the password, enter betting, which is set in local-deployment/docker-compose.yml:

```
psql -h 127.0.0.1 -d betting  -U betting -f bet-projection.sql
psql -h 127.0.0.1 -d betting  -U betting -f akka-persistence.sql
psql -h 127.0.0.1 -d betting  -U betting -f akka-projection.sql
```

To start a node, start sbt in the root of the Git repository and set local.conf as the configuration resource:
