```
sbt "-Dconfig.resource=local.conf"
```

Once the sbt server is up, enter

```
sbt:code> betting-house/run
```

To play around with the different calls, you can find examples in the README.md file of the betting-house project.

15.3.2 Running in Kubernetes

This section assumes a basic understanding of Kubernetes and databases. To deploy the application to Kubernetes, you need to do the following:

- Have a Kubernetes cluster available.
- Create a service account that your deployment should use. You can do this with the role.yml file in the root directory of the betting-house project.
- Create a Kubernetes deployment. You can do this with the deployment.yml file.
- Create a Docker image for the betting-house JAR.

To make a Kubernetes cluster available, run `minikube start`. (Follow the instructions in appendix A if you haven't already.)

The contents of role.yml and deployment.yml are nothing you haven't seen in chapter 13. Therefore, they are not repeated here. The only relevant information for what follows is the deployment name, since the pods use it: `my-deployment-name`. The other essential
