piece of information is the image used in deployment.yml, which is the name of the Docker image that wraps the application JAR. Let's look at how you create and name the image.

Creating the image with the JAR

You need to enable the plugins in build.sbt—`JavaAppPackaging` and `DockerPlugin`—to package the application into a JAR and that into a Docker image. Then set the Docker base image and open the ports for Akka Management, Akka Remote, the services, and the bet projection. Finally, assign a version to the image:

```
lazy val `betting-house` = project
    .in(file("betting-house"))
    .enablePlugins(AkkaGrpcPlugin, JavaAppPackaging, DockerPlugin)
    .settings(
      version := "0.1.1-SNAPSHOT",                                    ❶

      Compile / mainClass := Some("example.betting.Main"),            ❷

      dockerExposedPorts := Seq(8558, 2552, 9000, 9001,9002,9003),    ❸

      dockerBaseImage := "adoptopenjdk:11-jre-hotspot",               ❹

      dockerUsername := "yourusername",                               ❺

      libraryDependencies ++= Seq(
        ...                                                           ❻
      ))
```

❶ Version of the image

❷ Entry point of the application

❸ Opens the ports

❹ Sets the base image

❺ Registry inside the repository docker.io

❻ Dependencies go here.
