The open ports correspond to the following order:

1. Akka Management to expose the state of the nodes
2. Akka Remote to connect node actors with one another
3. The bet entity service
4. The market entity service
5. The wallet entity service
6. The bet projection query

Now you can publish the image by entering the following at the command line in the root directory of the Git repository:

```
sbt betting-house/docker:publish
```

You use deployment.yml and role.yml later.

Starting the application

Create the Kubernetes namespace where you want the database—and later, the application—to run:

```
$ cd betting-house/k8s-deployment                                    ❶
$ kubectl create ns akka-cluster                                     ❷
$ kubectl apply -f postgres-containers-db-deployment.yml -n akka-cluster  ❸
$ kubectl apply -f postgres-containers-db-service.yml -n akka-cluster     ❹
```

❶ From the root folder of the Git repository

❷ Creates the cluster

❸ Creates the database

❹ Creates a service to act as a proxy
