change `ignore` to `in`, and then execute the following from the command line:

```
$ sbt
sbt:code> chapter16/testOnly *CPUBoundedSpec
```

Here's the output of processing the 10 elements:

```
1.914s
1.765s
1.726s
1.793s
1.758s
1.743s
1.767s
1.841s
1.735s
1.751s

[info] Run completed in 18 seconds, 373 milliseconds.
```

The outputs appear on the screen one by one, almost reluctantly. Execution took 18 seconds for 10 elements. That is too slow. You can easily improve it with a small change.

MAPASYNC

Instead of using `map`, which executes each element in sequence, you can parallelize the execution by using `mapAsync` and setting the degree of parallelism. It is important to know that this operator guarantees the order of results. The result of the first element, even if it takes longer than the second, keeps its order, and it is always handled to the next stage before the second. `mapAsync` has the signature `f: Out => Future[T]`; therefore, you need to wrap the call in a future, which needs an execution context:
