```
db.containers.poolInitialSize=5
db.containers.poolMaxSize=100                    ❶
```

❶ To avoid overloading the database with connections

This `poolMaxSize` value should be chosen depending on the database type and settings. In a Postgres database, the default value is 100 (https://brandur.org/postgres-connections). `db.containers` makes it possible to refer to this database in the code with `Symbol("containers")` alone.

With these settings in place, you can read from the `containers` database using a basic database accessor in read-only mode:

```
import scalikejdbc.NamedDB

class CPUNonBoundedSpec ... {
  ...

  NamedDB(Symbol("containers")).readOnly
```

Add the query to retrieve the ID of each entry by searching for the sequence number:

```
        sql"select persistence_id from event_journal where sequence_number
        ➥= ${seqNum}"
          .map(rs => rs.string("persistence_id"))
          .first
          .apply()
  ...
}
```

You select only the `persistence_id` field and, if present, the first result, because you are making a query for a `sequence_number` that occurs only once. The result can be only one row or none.

You can wrap all this in a method to use it from the stream:
