```
class CPUNonBoundedSpec ... {
  ...

  def myGetPersistenceId(seqNum: Int): Option[String] = {
    val name: Option[String] = NamedDB(Symbol("containers")).readOnly {
      implicit session =>
        sql"select persistence_id from event_journal where sequence_number
        ➥= ${seqNum}"
          .map(rs => rs.string("persistence_id"))
          .first
          .apply()
    }
    name
  }
  ...
}
```

Now you can test this by establishing the connection and using the method described earlier for the stream. As usual, you should close the connection afterward:

```
class CPUNonBoundedSpec ... {
  ...

  "connecting to a db" should {
    "work" in {

      DBs.setup(Symbol("containers"))                                  ❶

      def myGetPersistenceId...

      val result = Source(1 to 100)
        .mapAsync(100)(each => Future(myGetPersistenceId(each % 10)))  ❷
        .map(println)
        .run()

      Await.result(result, 5.seconds)
      DBs.close('containers)                                           ❸

  }}

  ...
}
```

❶ Creates the connection pool out of the configuration
