```
      double lat = 1;
      double lon = 2;
}

service LocatorService {
      rpc Follow(google.protobuf.Empty) returns (stream Location) {}    ❸
}
```

❶ Input type import

❷ Output type

❸ Service returning a stream per call

This service, named `Follow`, provides a stream of `Location` elements. Don't pay much attention to the implementation of this service because it is mainly a dummy. The idea is that a car has this `LocatorServer` built in and passes its latitude and longitude to the service when the car is started. From there, the service changes its latitude and longitude depending on the car's movement.

For simplicity, you pass only the latitude to the service at startup, and the car's movement is simulated to increase linearly over time. It follows the same longitude as if driving in a straight line.

Start the server from the repository root directory by entering the following at the command line:

```
sbt "chapter16/runMain example.locator.grpc.LocatorServer 1"
```

The value `1` at the end of the command is the initial latitude of the `Location`.

The purpose of this dummy service is to show you two things in practice: `RestartSource` and a gRPC service with a stream as output, also called *server streaming* gRPC. You may remember the example of a unary call in chapter 11, where one request generated
