one response. Now one request generates a stream of responses—an infinite stream.

Here's how the service works, with a call to the service and its responses. You can find the implementation in the `LocatorServiceImpl` in the Git repository:

```
$ grpcurl -plaintext localhost:8080 LocatorService/Follow    ❶

                                                             ❷
{
  "lat": 1,
  "lon": -3.701101
}
{
  "lat": 2,
  "lon": -3.701101
}
{
  "lat": 3,
  "lon": -3.701101
}
...                                                          ❸
```

❶ Call to the service

❷ Infinite stream of responses, one element per second

❸ More responses not printed here

This output shows how a call to the service produces an infinite stream of responses. You get a stream that produces one element per second.

Now let's see how a source that can be restarted behaves when you stop the service. The test consumes this service for 90 seconds, giving you time to stop and restart the gRPC service before the test is finished. The test has a client for the locator service and a `RestartSource` that uses that service and can cope with the service being down.
