- Handling exceptions with `recover` only processes one last message before shutting down the stream. You should model exceptions as data to avoid this scenario and later use `divertTo` to change the final output of the elements. That way, the properly processed elements go to one sink and the others to another sink.
- Create sources that are restarted after a failure so the stream continues to consume items from the source after recovery. Depending on your strategy, you can drop the offending messages or treat the exceptions as data, modifying them to become like any other message in the stream.
