the necessary ideas to deal with latency, concurrency, and partial failures (see Jim Waldo et al., “A Note on Distributed Computing,” Sun Microsystems Laboratories, 1994, http://mng.bz/NmJx). Gregor Hohpe pointed out that when treating remote calls as local calls, "RPC is not an abstraction, it is an illusion” (YOW! Singapore 2017, http://mng.bz/DZJg). And recently he told me that nowadays, he would even rephrase and say “RPCs in their attempt at abstraction" to underline that the abstraction failed.

But all the work was not in vain. Some of the CORBA ideas were combined with the new XML standard in the form of an interface definition language (IDL) to define messages and their possible operations. As a result, the W3C and some other organizations joined forces to create the Web Services specification (https://www.w3.org/2002/ws/history.html).

Another common term in the software industry around 2000 was *enterprise service bus* (ESB). In the same year as the Web Services specification, Roy Schulte, the most senior analyst at Gartner at the time, coined the term ESB. If it can’t send and receive SOAP/HTTP messages or support Web Service Definition Language (WSDL), it’s not an ESB (see Jason Stamper, blog, 2005, https://techmonitor.ai/techonology/esb_inventor_ri). However, this does not complete the description of an ESB. Another important feature is the message bus (also called a *broker*), which is used for data transmission on the platform. The ESB design thus includes two types of communication: peer-to-peer via web services and message passing via the message bus.

It would be incomplete to define ESBs without mentioning the features of service discovery, routing, security, and monitoring. In 2003, Gartner coined the term *service-oriented architecture* (SOA);
